Lecture 6. Purely Functional Data structures

Functional Programming 2019/20

Frank Staals

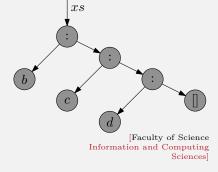

Goals

- ► Know the difference between persistent (purely functional) and ephemeral data structures,
- ▶ Be able to use persistent data structures,
- ▶ Define and work with custom data types

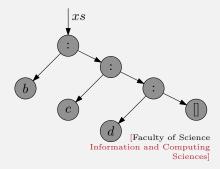

ightharpoonup What does x:xs look like in memory?

- ▶ What does x:xs look like in memory?
- ► Suppose that xs = b:c:d:[] for some b,c and d

 \blacktriangleright What does xs = b:c:d:[] look like in memory?

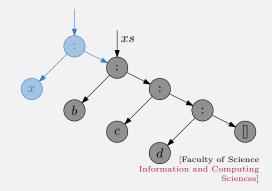

► What does x:xs look like in memory?

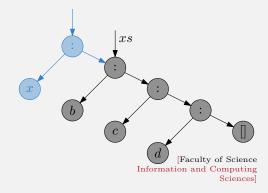

► What does x:xs look like in memory?

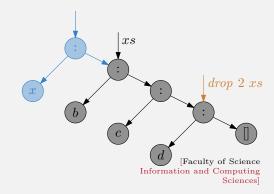

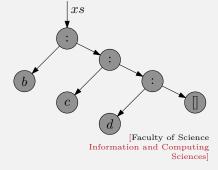

▶ What does drop 2 xs look like in memory?

▶ What does drop 2 xs look like in memory?

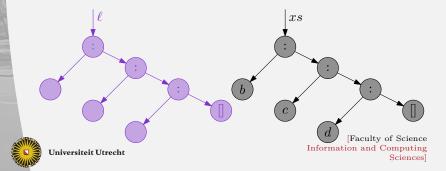

▶ What does 1 ++ xs look like in memory?

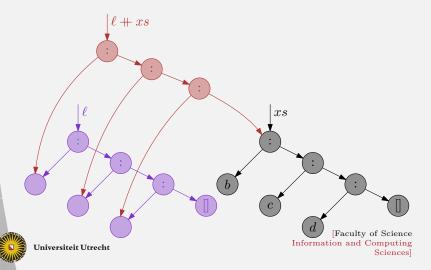

▶ What does 1 ++ xs look like in memory?

▶ What does 1 ++ xs look like in memory?

Persistent vs Ephemeral

- Data structures in which old versions are available are persistent data structures.
- ► Traditional data structures are ephemeral.

Persistent vs Ephemeral

- ► Advantages of persistent data structures:
 - Convenient to have both old and new:
 - Separation of concerns;
 - Compute subexpressions independently
 - Output may contain old versions:

Persistent vs Ephemeral

- ► Advantages of persistent data structures:
 - Convenient to have both old and new:
 - Separation of concerns;
 - Compute subexpressions independently
 - Output may contain old versions:

Can we get this for other data structures?

Yes*!

Can we get this for other data structures?

Yes*!

[*] for a lot of them

Successor Data Structure

- Store an set S of ordered elements s.t. we can efficiently find successor of a query q.
- ightharpoonup The successor of q is the smallest element in S larger or equal to q.

► Idea: Use an (unordered) list

```
type Successor a = [a]
```

▶ What should the type of our succOf function be?

► Idea: Use an (unordered) list

```
type Successor a = [a]
```

▶ What should the type of our succOf function be?

```
succOf :: Ord a => a -> Successor a -> Maybe a
```

```
succOf :: Ord a => a -> Successor a -> Maybe a
succOf q s = minimum' [ x | x <- s, x >= q]
where
  minimum' [] = Nothing
minimum' xs = Just (minimum xs)
```

```
succOf :: Ord a => a -> Successor a -> Maybe a
succOf q s = minimum' [ x | x <- s, x >= q]
where
minimum' [] = Nothing
minimum' xs = Just (minimum xs)
```

ightharpoonup Running time: O(n)

Implementing a Successor DS: Try 2, Ordered Lists

► Idea: Use an ordered list.

Implementing a Successor DS: Try 2, Ordered Lists

► Idea: Use an ordered list.

```
succOf q [] = Nothing

succOf q (x:s) | x < q = succOf q s

| otherwise = Just x
```

ightharpoonup Does not really help: running time is still O(n).

Implementing a Successor DS: Try 2, Ordered Lists

► Idea: Use an ordered list.

```
succOf q [] = Nothing

succOf q (x:s) | x < q = succOf q s

| otherwise = Just x
```

- ightharpoonup Does not really help: running time is still O(n).
- ▶ We need a better data structure.

Implementing a Successor DS: Try 3, BSTs

► Idea: Use a binary search tree.

Implementing a Successor DS: Queries

Implementing a Successor DS: Queries

Nice if the input tree happens to be balanced, i.e. of height $O(\log n)$

Making Balanced Trees

Suppose that the input is a sorted list, how to build a balanced tree?

Making Balanced Trees

Suppose that the input is a sorted list, how to build a balanced tree?

```
buildBalanced :: [a] -> Tree a
buildBalanced [] = Leaf
buildBalanced xs = Node | x | r
  where
    h = length xs 'div' 2
    (ls,x:rs) = splitAt h xs
    1 = buildBalanced ls
    r = buildBalanced rs
```

ightharpoonup Running time: $O(n \log n)$.

Dynamic Successor: Insert

► Can we add new elements to the set S?

Dynamic Successor: Insert

 \blacktriangleright Can we add new elements to the set S?

Dynamic Successor: Insert

 \blacktriangleright Can we add new elements to the set S?

- Notjustinsert x 1!
- Note that we are building new trees!

May unbalance the tree

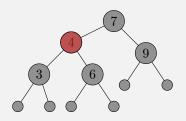

Repeatedly inserting elements unbalances the tree

```
> foldr insert Leaf [1..5]
Node (Node (Node (Node Leaf 1 Leaf) 2 Leaf) 3 Leaf
```

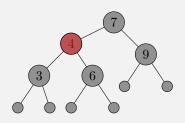

Self balancing trees: Red Black Trees

► Properties:

- 1) leaves are black
- 2) root is black
- 3) red nodes have black children
- 4) for any node, all paths to leaves have the same number of black children.

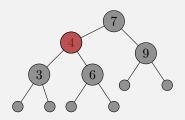

Self balancing trees: Red Black Trees

- Properties:
 - 1) leaves are black
 - 2) root is black
 - 3) red nodes have black children
 - 4) for any node, both children have the same blackheight
- blackHeight of a node = number of black children on any path from that node to its leaves.

Self balancing trees: Red Black Trees

- Properties:
 - 1) leaves are black
 - 2) root is black
 - 3) red nodes have black children
 - 4) for any node, both children have the same blackheight
- ightharpoonup Support queries and updates in $O(\log n)$ time.

Red Black Trees in Haskell

Red Black Trees in Haskell

Better:

► Enforces property 1. Other properties are more difficult to enforce in the type.

Implementing Queries and Inserts

- succOf more or less the same as before.
- ► Insert:

Implementing Insert

- Make sure black heights remain ok by replacing a black leaf by a red node.
- ► The only issue is red,red violations.
- Allow red,red violations with the root, but not below that.

Implementing Insert

- Make sure black heights remain ok by replacing a black leaf by a red node.
- ► The only issue is red,red violations.
- Allow red,red violations with the root, but not below that.

Implementing Insert

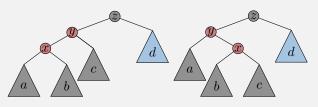

- Make sure black heights remain ok by replacing a black leaf by a red node.
- ► The only issue is red,red violations.
- Allow red,red violations with the root, but not below that.

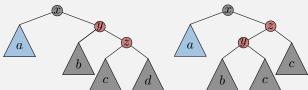

balance :: Color -> RBTree a -> a -> RBTree a

-> RBTree a

Rebalancing

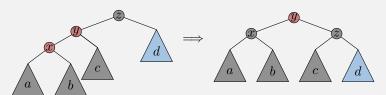

- ▶ The only potential issue is two red nodes near the root.
- ► There are only four configurations:

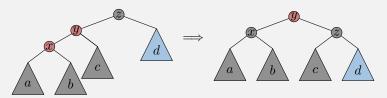

Rebalancing

► Make the root red, and its children black:

Rebalancing

▶ Make the root red, and its children black:

balance Black (Node Red (Node Red a x b) y c) z d = Node Red (Node Black a x b) y (Node Black c z d)

Rebalancing code

▶ Other cases are symmetric:

```
balance Black (Node Red (Node Red a x b) y c) z d =
   Node Red (Node Black a x b) y (Node Black c z d)
balance Black (Node Red a x (Node Red b y c)) z d =
   Node Red (Node Black a x b) y (Node Black c z d)
```

```
balance Black a x (Node Red (Node Red b y c) z d) =
    Node Red (Node Black a x b) y (Node Black c z d)
balance Black a x (Node Red b y (Node Red c z d)) =
    Node Red (Node Black a x b) y (Node Black c z d)
```

Rebalancing code

Other cases are symmetric:

```
balance Black (Node Red (Node Red a x b) y c) z d =
   Node Red (Node Black a x b) y (Node Black c z d)
balance Black (Node Red a x (Node Red b y c)) z d =
   Node Red (Node Black a x b) y (Node Black c z d)
```

```
balance Black a x (Node Red (Node Red b y c) z d) =
   Node Red (Node Black a x b) y (Node Black c z d)
balance Black a x (Node Red b y (Node Red c z d)) =
   Node Red (Node Black a x b) y (Node Black c z d)
```

balance c l x r
Node c l x r

Deleting

 \blacktriangleright What if we also want to remove elements from S?

Deleting

- \blacktriangleright What if we also want to remove elements from S?
- ightharpoonup Possible in $O(\log n)$ time with Red-Black trees, but a bit more messy.

Data structures in the Haskell Standard Library

- ► Self balancing BST Implementation available in Data. Set
- ▶ Often useful to store additional information: Data.Map.

```
lookup :: Ord k \Rightarrow k \rightarrow Map k v \rightarrow Maybe v
```

Data structures in the Haskell Standard Library

- Self balancing BST Implementation available in Data. Set
- ▶ Often useful to store additional information: Data.Map.

```
lookup :: Ord k => k -> Map k v -> Maybe v
```

► Finite Sequences: Data.Sequence, allow fast access to front and back.

Data structures in the Haskell Standard Library

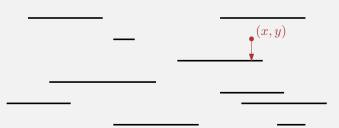

- Self balancing BST Implementation available in Data. Set
- ▶ Often useful to store additional information: Data.Map.

```
lookup :: Ord k \Rightarrow k \rightarrow Map k v \rightarrow Maybe v
```

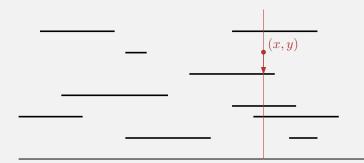

- ► Finite Sequences: Data.Sequence, allow fast access to front and back.
- ▶ All these data structures are persistent.

ightharpoonup Can we quickly find the platform directly below Mario at (x,y)?

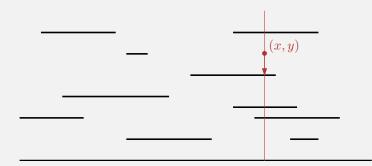

lackbox Can we quickly find the platform directly below Mario at (x,y)?

▶ Easy if we had the platforms intersecting the vertical line at x in a Set or Map: find predecessor of y.

lackbox Can we quickly find the platform directly below Mario at (x,y)?

What happens when vertical line starts/stops to intersect a platform?

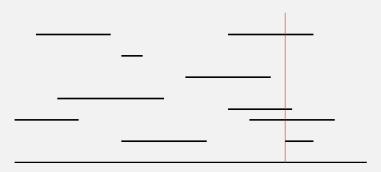

lackbox Can we quickly find the platform directly below Mario at (x,y)?

What happens when vertical line starts/stops to intersect a platform?

lackbox Can we quickly find the platform directly below Mario at (x,y)?

What happens when vertical line starts/stops to intersect a platform?

- lacktriangle Can we quickly find the platform directly below Mario at (x,y)?
- ► What happens when vertical line starts/stops to intersect a platform?

- lackbox Can we quickly find the platform directly below Mario at (x,y)?
- What happens when vertical line starts/stops to intersect a platform?
- ► Add or remove a platform from the Set

- ightharpoonup Can we quickly find the platform directly below Mario at (x,y)?
- What happens when vertical line starts/stops to intersect a platform?
- ▶ Add or remove a platform from the Set
- ► Since Set is persistent, old versions remain in tact. Store them in a Map.

- ► Can we quickly find the platform directly below Mario at (x,y)?
- What happens when vertical line starts/stops to intersect a platform?
- ► Add or remove a platform from the Set
- Since Set is persistent, old versions remain in tact. Store them in a Map.
- ► To answer a query: go to the version at time x using a successor query, and find predecessor of y.

Homework: Verifying Red-Black Tree Properties

► Write a function validRBTree :: RBTree a -> Bool that checks if a given RBTree a satisfies all red-black tree properties.
